This software consists of 3 parts. First of all, it is possible to select several audio files in the player, drag them into the sound player, then activate the second part. Now you have a small control-panel, where you can change the sound-source with the sound-player, choose the type of re-arrangement, transpose the sound or even change the instruments. This software is more oriented for amateur musicians and DJs > than for professional audio engineers. Now, you can remix your favorite tracks with this software for free.Q: Are bi-directional relations any different in the programming world? I'm talking about functional languages like Haskell and Prolog, where expressions are evaluated left-to-right. Do we need some special facilities to handle the case where two or more relations are read at the same time, i.e. a situation like this: [1,2,3] 1 or [1,2,3] 3 where the first line is evaluated as [1,2,3] 1 and the second line as [1,2,3] 3? Or do functional languages always support that without any special syntax? A: No. In functional programming, the order of evaluation is independent of the order of elements in a list. This is known as non-strict evaluation, or currying. There are certain programming languages where evaluation does depend on the order of the elements, either implicitly (i.e. they don't really support non-strict evaluation, but an operation is built using the full evaluation order) or explicitly (e.g. because they have lazy evaluation, with the result of evaluation being a function of the evaluated elements). In non-functional languages, I've seen examples of ways to simulate non-strict evaluation (by asking the programmer to "memoize" the value they want to return for the entire expression, because the result will only be required later), but these tend to be ugly and often only work because the compiler can force ordering. So, no, programming languages that don't support 82157476af
